# Allograft Procedure

Recession can be treated in a variety of methods including a free gingival graft, connective tissue graft, coronal positioned graft or an allograft procedure. Due to a variety of factors our office chose to treat the area below with an allograft procedure. Cadaver tissue was used to thicken the amount of connective tissue. The patient had uneventful healing and a low level of discomfort or other post surgical problem. As can be seen from the final picture, complete root coverage was obtained. Our office has extensive experience in treating areas such as the case highlighted below.
